

Lecture 8: Discretization and Implementation of Continuous-time Design

Big picture

Discrete-time frequency response

Discretization of continuous-time design

Aliasing and anti-aliasing

Big picture

why are we learning this:

- ▶ nowadays controllers are implemented in discrete-time domain
- ▶ implementation media: digital signal processor, field-programmable gate array (FPGA), etc
- ▶ either: controller is designed in continuous-time domain and implemented digitally
- ▶ or: controller is designed directly in discrete-time domain

Frequency response of LTI SISO digital systems

$$a \sin(\omega T_s k) \longrightarrow \boxed{G(z)} \longrightarrow b \sin(\omega T_s k + \phi) \text{ at steady state}$$

- ▶ sampling time: T_s
- ▶ $\phi(e^{j\omega T_s})$: phase difference between the output and the input
- ▶ $M(e^{j\omega T_s}) = b/a$: magnitude difference

continuous-time frequency response:

$$G(j\omega) = G(s)|_{s=j\omega} = |G(j\omega)| e^{j\angle G(j\omega)}$$

discrete-time frequency response:

$$\begin{aligned} G(e^{j\omega T_s}) &= G(z)|_{z=e^{j\omega T_s}} = |G(e^{j\omega T_s})| e^{j\angle G(e^{j\omega T_s})} \\ &= M(e^{j\omega T_s}) e^{j\phi(e^{j\omega T_s})} \end{aligned}$$

Sampling

sufficient samples must be collected (i.e., fast enough sampling frequency) to recover the frequency of a continuous-time sinusoidal signal (with frequency ω in rad/sec)

Figure: Sampling example (source: Wikipedia.org)

- ▶ the sampling frequency $= \frac{2\pi}{T_s}$
- ▶ Shannon's sampling theorem: the Nyquist frequency ($\triangleq \frac{\pi}{T_s}$) must satisfy

$$-\frac{\pi}{T_s} < \omega < \frac{\pi}{T_s}$$

Approximation of continuous-time controllers

bilinear transform

formula:

$$\boxed{s = \frac{2}{T_s} \frac{z-1}{z+1} \quad z = \frac{1 + \frac{T_s}{2}s}{1 - \frac{T_s}{2}s}} \quad (1)$$

intuition:

$$z = e^{sT_s} = \frac{e^{sT_s/2}}{e^{-sT_s/2}} \approx \frac{1 + \frac{T_s}{2}s}{1 - \frac{T_s}{2}s}$$

implementation: start with $G(s)$, obtain the discrete implementation

$$G_d(z) = G(s) \Big|_{s = \frac{2}{T_s} \frac{z-1}{z+1}} \quad (2)$$

Bilinear transformation maps the closed left half s -plane to the closed unit ball in z -plane

Stability reservation: $G(s)$ stable $\iff G_d(z)$ stable

Approximation of continuous-time controllers

history

Bilinear transform is also known as Tustin transform.

Arnold Tustin (16 July 1899 – 9 January 1994):

- ▶ British engineer, Professor at University of Birmingham and at Imperial College London
- ▶ served in the Royal Engineers in World War I
- ▶ worked a lot on electrical machines

Approximation of continuous-time controllers

frequency mismatch in bilinear transform

$$\left. \frac{2}{T_s} \frac{z-1}{z+1} \right|_{z=e^{j\omega T_s}} = \frac{2}{T_s} \frac{e^{j\omega T_s/2} (e^{j\omega T_s/2} - e^{-j\omega T_s/2})}{e^{j\omega T_s/2} (e^{j\omega T_s/2} + e^{-j\omega T_s/2})} = j \overbrace{\frac{2}{T_s} \tan\left(\frac{\omega T_s}{2}\right)}^{\omega_v}$$

$G(s)|_{s=j\omega}$ is the true frequency response at ω ; yet bilinear implementation gives,

$$G_d(e^{j\omega T_s}) = G(s)|_{s=j\omega_v} \neq G(s)|_{s=j\omega}$$

Lecture 8: Discretization and Implementation of Continuous-time Design

ME233 8-6

Approximation of continuous-time controllers

bilinear transform with prewarping

goal: extend bilinear transformation such that

$$G_d(z)|_{z=e^{j\omega T_s}} = G(s)|_{s=j\omega}$$

at a particular frequency ω_p

solution:

$$\boxed{s = p \frac{z-1}{z+1}, \quad z = \frac{1 + \frac{1}{p}s}{1 - \frac{1}{p}s}, \quad p = \frac{\omega_p}{\tan\left(\frac{\omega_p T_s}{2}\right)}}$$

which gives

$$G_d(z) = G(s)|_{s=\frac{\omega_p}{\tan\left(\frac{\omega_p T_s}{2}\right)} \frac{z-1}{z+1}}$$

and

$$\left. \frac{\omega_p}{\tan\left(\frac{\omega_p T_s}{2}\right)} \frac{z-1}{z+1} \right|_{z=e^{j\omega_p T_s}} = j \frac{\omega_p}{\tan\left(\frac{\omega_p T_s}{2}\right)} \tan\left(\frac{\omega_p T_s}{2}\right)$$

Lecture 8: Discretization and Implementation of Continuous-time Design

ME233 8-7

Approximation of continuous-time controllers

bilinear transform with prewarping

choosing a prewarping frequency ω_p :

- ▶ must be below the Nyquist frequency:

$$0 < \omega_p < \frac{\pi}{T_s}$$

- ▶ standard bilinear transform corresponds to the case where $\omega_p = 0$
- ▶ the best choice of ω_p depends on the important features in control design

example choices of ω_p :

- ▶ at the cross-over frequency (which helps preserve phase margin)
- ▶ at the frequency of a critical notch for compensating system resonances

Sampling and aliasing

sampling maps the continuous-time frequency

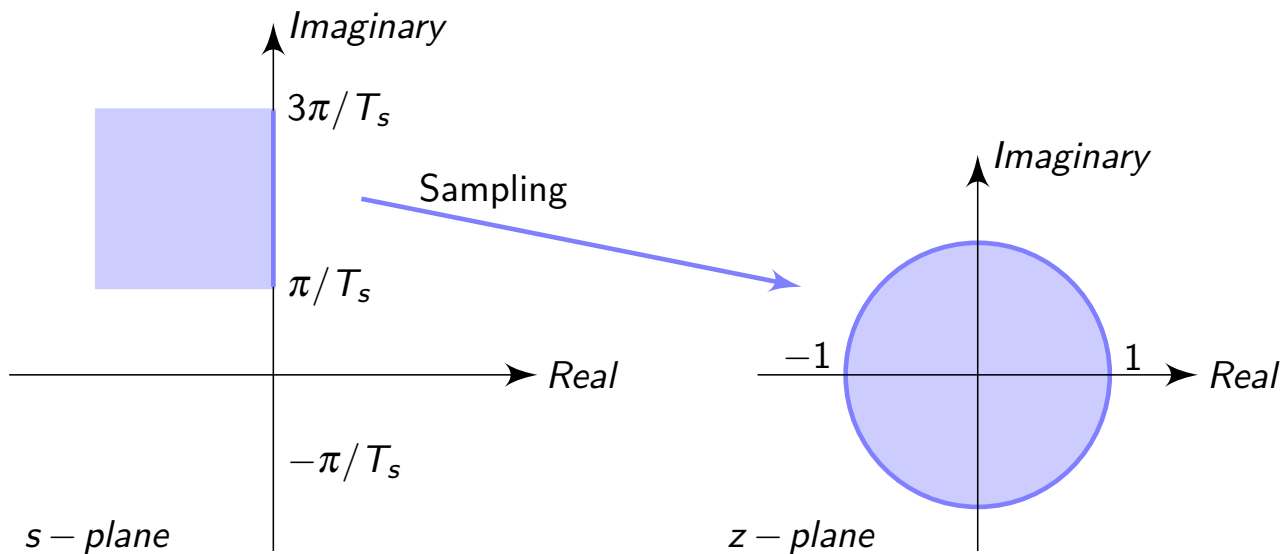

$$-\frac{\pi}{T_s} < \omega < \frac{\pi}{T_s}$$

onto the unit circle

Sampling and aliasing

sampling also maps the continuous-time frequencies $\frac{\pi}{T_s} < \omega < 3\frac{\pi}{T_s}$, $3\frac{\pi}{T_s} < \omega < 5\frac{\pi}{T_s}$, etc, onto the unit circle

Sampling and aliasing

Example (Sampling and Aliasing)

$T_s = 1/60$ sec (Nyquist frequency 30 Hz).

a continuous-time 10-Hz signal $[10 \text{ Hz} \leftrightarrow 2\pi \times 10 \text{ rad/sec} \in (-\pi/T_s, \pi/T_s)]$

$$y_1(t) = \sin(2\pi \times 10t)$$

is sampled to

$$y_1(k) = \sin\left(2\pi \times \frac{10}{60}k\right) = \sin\left(2\pi \times \frac{1}{6}k\right)$$

a 70-Hz signal $[2\pi \times 70 \text{ rad/sec} \in (\pi/T_s, 3\pi/T_s)]$

$$y_2(t) = \sin(2\pi \times 70t)$$

is sampled to

$$y_2(k) = \sin\left(2\pi \times \frac{70}{60}k\right) = \sin\left(2\pi \times \frac{1}{6}k\right) \equiv y_1(k)!$$

Anti-aliasing

need to avoid the negative influence of *aliasing* beyond the Nyquist frequencies

- ▶ sample faster: make π/T_s large; the sampling frequency should be high enough for good control design
- ▶ anti-aliasing: perform a low-pass filter to filter out the signals $|\omega| > \pi/T_s$

Summary

1. Big picture
2. Discrete-time frequency response
3. Approximation of continuous-time controllers
4. Sampling and aliasing

Sampling example

- ▶ continuous-time signal

$$y(t) = \begin{cases} e^{-at}, & t \geq 0 \\ 0, & t < 0 \end{cases}, \quad a > 0$$

$$\mathcal{L}\{y(t)\} = \frac{1}{s+a}$$

- ▶ discrete-time sampled signal

$$y(k) = \begin{cases} e^{-aT_s k}, & k \geq 0 \\ 0, & k < 0 \end{cases}$$

$$\mathcal{Z}\{y(k)\} = \frac{1}{1 - z^{-1}e^{-aT_s}}$$

- ▶ sampling maps the continuous-time pole $s_i = -a$ to the discrete-time pole $z_i = e^{-aT_s}$, via the mapping

$$z_i = e^{s_i T_s}$$
