Lecture 13: Internal Model Principle and Repetitive Control

Big picture

review of integral control in PID design example:

$$0 \longrightarrow 0 \xrightarrow{E(s)} C(s) \xrightarrow{P(s)} P(s)$$

where

$$P(s) = \frac{1}{ms+b}, \ C(s) = k_p + k_i \frac{1}{s} + k_d s, \ k_p, k_i, k_d > 0$$

• the integral action in PID control perfectly rejects (asymptotically) constant disturbances $(D(s) = d_o/s)$:

$$E(s) = \frac{-P(s)}{1 + P(s)C(s)}D(s) = \frac{-d_o}{(m + k_d)s^2 + (k_p + b)s + k_i}$$
$$\Rightarrow e(t) \rightarrow 0$$

Big picture

review of integral control in PID design

$$0 \longrightarrow 0 \xrightarrow{E(s)} C(s) \xrightarrow{P(s)} Y(s)$$

the "structure" of the reference/disturbance is built into the integral controller:

controller:

$$C(s) = k_p + k_i \frac{1}{s} + k_d s = \left[\frac{1}{s}\right] \left(k_d s^2 + k_p s + k_i\right)$$

constant disturbance:

$$d(t) = d_o \Leftrightarrow \mathcal{L}\left\{d(t)\right\} = \boxed{\frac{1}{s}}d_o$$

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-2

General case: internal model principle (IMP)

Theorem (Internal Model Principle)

$$R(s) \xrightarrow{+} C(s) = \frac{B_c(s)}{A_c(s)}$$

$$P(s) = \frac{B_d(s)}{A_d(s)}$$

$$P(s) = \frac{B_p(s)}{A_p(s)}$$

$$+ P(s) = \frac{B_p(s)}{A_p(s)}$$

Assume $B_p(s) = 0$ and $A_d(s) = 0$ do not have common roots. If the closed loop is asymptotically stable, and $A_c(s)$ can be factorized as $A_c(s) = A_d(s)A_c'(s)$, then the disturbance is asymptotically rejected.

General case: internal model principle (IMP)

$$R(s) \xrightarrow{+} C(s) = \frac{B_{c}(s)}{A_{c}(s)}$$

$$+ C(s) = \frac{B_{c}(s)}{A_{c}(s)}$$

Proof: The steady-state error response to the disturbance is

$$E(s) = \frac{-P(s)}{1 + P(s)C(s)}D(s) = \frac{-B_{p}(s)A_{c}(s)}{A_{p}(s)A_{c}(s) + B_{p}(s)B_{c}(s)}\frac{B_{d}(s)}{A_{d}(s)}$$
$$= \frac{-B_{p}(s)A_{c}^{'}(s)B_{d}(s)}{A_{p}(s)A_{c}(s) + B_{p}(s)B_{c}(s)}$$

where all roots of $A_p(s)A_c(s)+B_p(s)B_c(s)=0$ are on the left half plane. Hence $e(t)\to 0$

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-4

Internal model principle

discrete-time case:

Theorem (Discrete-time IMP)

$$\begin{array}{c|c}
R(z^{-1})_{+} & E(z^{-1}) \\
\hline
 & A_{c}(z^{-1}) \\
\hline
 & A_{c}(z^{-1})
\end{array}$$

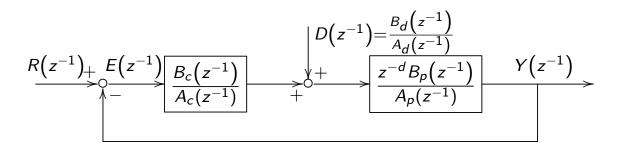

$$\begin{array}{c|c}
P(z^{-1}) = \frac{B_{d}(z^{-1})}{A_{d}(z^{-1})} \\
\hline
 & Z^{-d}B_{p}(z^{-1}) \\
\hline
 & A_{p}(z^{-1})
\end{array}$$

Assume $B_p\left(z^{-1}\right)=0$ and $A_d\left(z^{-1}\right)=0$ do not have common zeros. If the closed loop is asymptotically stable, and $A_c\left(z^{-1}\right)$ can be factorized as $A_c\left(z^{-1}\right)=A_d\left(z^{-1}\right)A_c'\left(z^{-1}\right)$, then the disturbance is asymptotically rejected.

Proof: analogous to the continuous-time case.

Internal model principle

the disturbance structure:

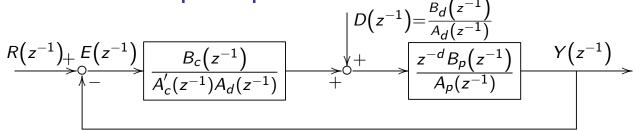

example disturbance structures:

$$\begin{array}{c|c} d(k) & A_d(z^{-1}) \\ \text{constant } d_o & 1-z^{-1} \\ \cos(\omega_0 k) \text{ and } \sin(\omega_0 k) & 1-2z^{-1}\cos(\omega_0)+z^{-2} \\ \text{shifted ramp signal } d(k)=\alpha k+\beta & 1-2z^{-1}+z^{-2} \\ \text{periodic: } d(k)=d(k-N) & 1-z^{-N} \end{array}$$

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-6

Internal model principle

observations:

- ▶ the controller contains a "counter disturbance" generator
- high-gain control: the open-loop frequency response

$$P\left(e^{-j\omega}\right)C\left(e^{-j\omega}\right) = \frac{e^{-dj\omega}B_{p}\left(e^{-j\omega}\right)B_{c}\left(e^{-j\omega}\right)}{A_{p}\left(e^{-j\omega}\right)A_{c}'\left(e^{-j\omega}\right)A_{d}\left(e^{-j\omega}\right)}$$

is large at frequencies where $A_d(e^{-j\omega})=0$

▶ $D(z^{-1}) = B_d(z^{-1})/A_d(z^{-1})$ means d(k) is the impulse response of $B_d(z^{-1})/A_d(z^{-1})$:

$$A_d(z^{-1}) d(k) = B_d(z^{-1}) \delta(k)$$

Outline

1. Big Picture

review of integral control in PID design

2. Internal Model Principle

theorems typical disturbance structures

3. Repetitive Control

use of internal model principle design by pole placement design by stable pole-zero cancellation

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-8

Repetitive control

Repetitive control focus on attenuating periodic disturbances with

$$A_d\left(z^{-1}\right) = 1 - z^{-N}$$

Control structure:

$$R(z^{-1}) + E(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})}$$

$$Y(z^{-1}) + E(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})}$$

$$Y(z^{-1}) + Z(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})}$$

$$Y(z^{-1}) + Z(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})}$$

It remains to design $B_{c}\left(z^{-1}\right)$ and $A_{c}^{'}\left(z^{-1}\right)$. We discuss two methods:

- pole placement
- (partial) cancellation of plant dynamics: prototype repetitive control

1, Pole placement: prerequisite

Theorem

Consider $G(z) = \frac{\beta(z)}{\alpha(z)} = \frac{\beta_1 z^{n-1} + \beta_2 z^{n-2} + \dots + \beta_n}{z^n + \alpha_1 z^{n-1} + \dots + \alpha_n}$. $\alpha(z)$ and $\beta(z)$ are coprime (no common roots) iff S (Sylvester matrix) is nonsingular:

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-10

1, Pole placement: prerequisite

Example:

$$G(z) = \frac{\beta_1 z^{n-1} + \beta_2 z^{n-2} + \dots + \beta_n}{z^n + \alpha_1 z^{n-1} + \dots + \alpha_n} = \frac{z^{n-1} + \alpha_1 z^{n-2} + \dots + \alpha_{n-1}}{z^n + \alpha_1 z^{n-1} + \dots + \alpha_{n-1} z + 0}$$

i.e.

$$eta_1 = 1$$
 $eta_i = lpha_{i-1} \ orall i \geq 2$
 $lpha_n = 0$

 $\alpha(z)$ and $\beta(z)$ are not coprime, and S is clearly singular.

1, Pole placement: big picture

Disturbance model: $A_d(z^{-1}) = 1 - z^{-N}$

Pole placement assigns the closed-loop characteristic equation:

$$z^{-d}B_{p}(z^{-1})B_{c}(z^{-1}) + A_{p}(z^{-1})A'_{c}(z^{-1})A_{d}(z^{-1})$$

$$= \underbrace{1 + \eta_{1}z^{-1} + \eta_{2}z^{-2} + \dots + \eta_{q}z^{-q}}_{\eta(z^{-1})}$$

which is in the structure of a Diophantine equation.

Design procedure: specify the desired closed-loop dynamics $\eta(z^{-1})$; match coefficients of z^{-i} on both sides to get $B_c(z^{-1})$ and $A'_c(z^{-1})$.

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-12

1, Pole placement: big picture

Diophantine equation in Pole placement:

$$z^{-d}B_{p}(z^{-1})B_{c}(z^{-1}) + A_{p}(z^{-1})A'_{c}(z^{-1})A_{d}(z^{-1})$$

$$= \underbrace{1 + \eta_{1}z^{-1} + \eta_{2}z^{-2} + \dots + \eta_{q}z^{-q}}_{\eta(z^{-1})}$$

Questions:

- what are the constraints for choosing $\eta(z^{-1})$?
- how to guarantee unique solution in Diophantine equation?

Design and analysis procedure

General procedure of control design:

- Problem definition
- Control design for solution (current stage)
- Prove stability
- Prove stability robustness
- Case study or implementation results

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-14

1, Pole placement: details

Theorem (Diophantine equation)

$$egin{aligned} \eta\left(z^{-1}
ight) &= 1 + \eta_1 z^{-1} + \eta_2 z^{-2} + \dots + \eta_q z^{-q} \ lpha\left(z^{-1}
ight) &= 1 + lpha_1 z^{-1} + \dots + lpha_n z^{-n} \ eta\left(z^{-1}
ight) &= eta_1 z^{-1} + eta_2 z^{-2} + \dots + eta_n z^{-n} \end{aligned}$$

The Diophantine equation

$$\alpha\left(z^{-1}\right)\sigma\left(z^{-1}\right)+\beta\left(z^{-1}\right)\gamma\left(z^{-1}\right)=\eta\left(z^{-1}\right)$$

can be solved uniquely for $\sigma\left(z^{-1}\right)$ and $\gamma\left(z^{-1}\right)$

$$\sigma\left(z^{-1}\right) = 1 + \sigma_1 z^{-1} + \dots + \sigma_{n-1} z^{-(n-1)}$$
 $\gamma\left(z^{-1}\right) = \gamma_0 + \gamma_1 z^{-1} + \dots + \gamma_{n-1} z^{-(n-1)}$

if the numerators of $\alpha\left(z^{-1}\right)$ and $\beta\left(z^{-1}\right)$ are coprime and $\deg\left(\eta\left(z^{-1}\right)\right)=q\leq 2n-1$

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-15

1, Pole placement: details

Proof of Diophantine equation Theorem (key ideas):

$$\alpha\left(z^{-1}\right)\underbrace{\sigma\left(z^{-1}\right)}_{\text{unknown}} + \beta\left(z^{-1}\right)\underbrace{\gamma\left(z^{-1}\right)}_{\text{unknown}} = \eta\left(z^{-1}\right)$$

Matching the coefficients of z^{-i} gives (see one numerical example in

course reader)

$$egin{array}{c|c} \sigma_1 \ \sigma_2 \ dots \ \sigma_{n-1} \ \gamma_0 \ dots \ \gamma_{n-1} \ \end{array} = egin{array}{c|c} lpha_1 \ lpha_2 \ dots \ lpha_n \ 0 \ dots \ \eta_{n-1} \ \eta_n \ dots \ \eta_{2n-1} \ \end{array}$$

The coprime condition assures S is invertible. $\deg \eta\left(z^{-1}\right) \leq 2n-1$ assures the proper dimension on the right hand side of the equality.

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-16

2, Prototype repetitive control: simple case

$$\begin{array}{c|c}
R(z^{-1}) + E(z^{-1}) & D(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})} \\
 & + & = \\
C(z^{-1}) + & + & = \\
\hline
C(z^{-1}) + & + & = \\
C(z^{-1}) + & + & = \\
\hline
A_p(z^{-1}) + & +$$

$$A_d\left(z^{-1}\right) = 1 - z^{-N}$$

If all poles and zeros of the plant are stable, then prototype repetitive control uses $\begin{pmatrix} -N+d & (-1) \end{pmatrix}$

$$C(z^{-1}) = \frac{k_r z^{-N+d} A_p(z^{-1})}{(1-z^{-N}) B_p(z^{-1})}$$

Theorem (Prototype repetitive control)

Under the assumptions above, the closed-loop system is asymptotically stable for $0 < k_r < 2$

2, Prototype repetitive control: stability

Proof of Theorem on prototype repetitive control: From

$$1 + \frac{k_r z^{-N+d} A_p(z^{-1})}{(1-z^{-N}) B_p(z^{-1})} \frac{z^{-d} B_p(z^{-1})}{A_p(z^{-1})} = 0$$

the closed-loop characteristic equation is

$$A_{p}(z^{-1})B_{p}(z^{-1})\left[1-(1-k_{r})z^{-N}\right]=0$$

- ▶ roots of $A_p(z^{-1})B_p(z^{-1})=0$ are all stable
- roots of $1 (1 k_r) z^{-N} = 0$ are

$$|1 - k_r|^{\frac{1}{N}} e^{j\frac{2\pi i}{N}}, \ i = 0, \pm 1, \dots, \ \text{for} \ 0 < k_r \le 1$$
 $|1 - k_r|^{\frac{1}{N}} e^{j\left(\frac{2\pi i}{N} + \frac{\pi}{N}\right)}, \ i = 0, \pm 1, \dots, \ \text{for} \ 1 < k_r$

which are all inside the unit circle

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-18

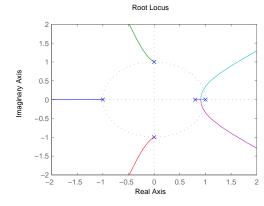

2, Prototype repetitive control: stability robustness

Consider the case with plant uncertainty

$$\xrightarrow{r(k)_{+}} \xrightarrow{(1-z^{-N})B_{p}(z^{-1})} \xrightarrow{+} \xrightarrow{d(k)} \xrightarrow{z^{-d}B_{p}(z^{-1})} (1+\Delta(z^{-1})) \xrightarrow{y(k)}$$

N open-loop poles on the unit circle

Root locus example:
$$N=4$$
, $1+\Delta\left(z^{-1}\right)=q/\left(z-p\right)$

 $\forall k_r > 0$, the closed-loop system is now unstable!

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-19

2, Prototype repetitive control: stability robustness

$$\xrightarrow{r(k)_{+}} C(z^{-1}) \xrightarrow{+} \frac{d(k)}{z^{-d}B_{\rho}(z^{-1})} (1 + \Delta(z^{-1})) \xrightarrow{y(k)}$$

To make the controller robust to plant uncertainties, do instead

$$C(z^{-1}) = \frac{k_r q(z, z^{-1}) z^{-N+d} A_p(z^{-1})}{(1 - q(z, z^{-1}) z^{-N}) B_p(z^{-1})}$$
(1)

 $q(z,z^{-1})$: low-pass filter. e.g. zero-phase low pass $\frac{\alpha_1 z^{-1} + \alpha_0 + \alpha_1 z}{\alpha_0 + 2\alpha_1}$

which shifts the marginary stable open-loop poles to be inside the unit circle:

$$A_{p}(z^{-1}) B_{p}(z^{-1}) \left[1 - (1 - k_{r}) q(z, z^{-1}) z^{-N}\right] = 0$$

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-20

2, Prototype repetitive control: extension

$$\begin{array}{c|c}
R(z^{-1}) + E(z^{-1}) & D(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})} \\
 & + & = \underbrace{C(z^{-1}) + E(z^{-1})}_{A_p(z^{-1})} & Y(z^{-1}) \\
 & + & = \underbrace{C(z^{-1}) + E(z^{-1})}_{A_p(z^{-1})} & Y(z^{-1})
\end{array}$$

If poles of the plant are stable but **NOT** all zeros are stable, let $B_p(z^{-1}) = B_p^-(z^{-1})B_p^+(z^{-1})$ [$B_p^-(z^{-1})$ —the uncancellable part] and

$$C(z^{-1}) = \frac{k_r z^{-N+\mu} A_p(z^{-1}) B_p^{-}(z) z^{-\mu}}{(1-z^{-N}) B_p^{+}(z^{-1}) z^{-d} b}, \ b > \max_{\omega \in [0,\pi]} |B_p^{-}(e^{j\omega})|^2$$
 (2)

Similar as before, can show that the closed-loop system is stable (in-class exercise).

2, Prototype repetitive control: extension

Exercise: analyze the stability of

$$\begin{array}{c|c}
 & D(z^{-1}) = \frac{B_d(z^{-1})}{A_d(z^{-1})} \\

$$C(z^{-1}) = \frac{k_r z^{-N+\mu} A_p(z^{-1}) B_p^{-}(z) z^{-\mu}}{(1-z^{-N}) B_p^{+}(z^{-1}) z^{-d} b}, \ b > \max_{\omega \in [0,\pi]} |B_p^{-}(e^{j\omega})|^2$$
(3)

$$\text{Key steps: } \left| \frac{B_p^-(e^{j\omega})B_p^-(e^{-j\omega})}{b} \right| < 1; \left| \frac{k_r B_p^-(e^{j\omega})B_p^-(e^{-j\omega})}{b} - 1 \right| < 1; \text{ all }$$

roots from

$$z^{-N} \left[\frac{k_r B_p^-(z) B_p^-(z^{-1})}{b} - 1 \right] + 1 = 0$$

are inside the unit circle.

Lecture 13: Internal Model Principle and Repetitive Control

ME233 13-22

2, Prototype repetitive control: extension

$$\xrightarrow{r(k)_{+}} C(z^{-1}) \xrightarrow{+} C(z^{-1}) \xrightarrow{r(k)_{+}} (1 + \Delta(z^{-1}))$$

Robust version in the presence of plant uncertainties:

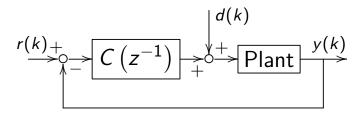

$$C(z^{-1}) = \frac{k_r z^{-N+\mu} q(z, z^{-1}) A_p(z^{-1}) B_p^{-}(z) z^{-\mu}}{(1 - q(z, z^{-1}) z^{-N}) B_p^{+}(z^{-1}) z^{-d} b}$$
(4)

where

$$q(z,z^{-1})$$
: low-pass filter. e.g. zero-phase low pass $\frac{\alpha_1 z^{-1} + \alpha_0 + \alpha_1 z}{\alpha_0 + 2\alpha_1}$

and μ is the order of $B_p^-(z)$

Example

disturbance period: N = 10; nominal plant:

$$\frac{z^{-d}B_{p}(z^{-1})}{A_{p}(z^{-1})} = \frac{z^{-1}}{(1-0.8z^{-1})(1-0.7z^{-1})}$$

$$C(z^{-1}) = k_{r} \frac{(1-0.8z^{-1})(1-0.7z^{-1})q(z,z^{-1})z^{-10}}{z^{-1}(1-q(z,z^{-1})z^{-10})}$$
